

Superheat™

> THE HEATER THAT PAYS YOU BACK_

From Thermal Hardware to Financial Infrastructure

Network strategy · live unit economics · the debt machine – three-part research, in full

THE THESIS

The Product Isn't the Heater. It Isn't Even the Compute.

Every great financing business runs the same loop. Dealerships run it on cars. Carvana industrialized it. Solar turned 25 years of electricity payments into an asset class.

Originate → Package → Sell → Recycle capital → Repeat

Superheat runs it on heat: every installed unit originates a contracted compute cash flow. The high-margin business is manufacturing, packaging, and distributing that cash flow — and the network finances its own growth.

THE REFRAME

The Others Just Heat Water. An H1 Originates an Asset.

10~~0~~ yr

Asset life

Heater shell outlives its GPUs; modules swap at year 5–6 and restart the curve

2

Cash legs per unit

Variable compute rental income + fixed contracted heat-service fees

2-in-1

Dual collateral

If compute softens, it's still a working water heater serving a standing heat demand

Structurally identical to a solar lease or a financed auto: one hardware placement throwing off a long-dated, contracted, predictable cash flow. Once you see the fleet as a pool of ten-year cash flows, the entire securitization playbook from autos and solar maps directly onto it.

THE PLAYBOOK, PORTED

Same Machine. Better Asset.

STAGE	CARVANA	SUNRUN	SUPERHEAT
Originate	Write the auto loan	Sign the 20-yr lease	Install the heater = 10-yr compute contract
Season	Collect payments	Energize + meter	Meter uptime + compute delivered — build the tape
Package	Pool loans → ABS	Pool leases → ABS	Pool nodes → compute-backed securities
Distribute	Insurers, pensions, funds	Insurers, pensions, funds	Same buyers — already hunting this exposure
Recycle	Fund new loans	Fund new installs	Fund the next 10,000 units — no dilution
Keep	Servicing fees (0.5–2%/yr)	O&M + servicing	Orchestration + servicing — never sold

The edge: solar collateral only **costs** the homeowner money. A Superheat unit **pays** them — the underwriting feature no solar lender ever had.

WHERE THE MONEY ACTUALLY IS

Four Layers. The Box Is the Cheapest One.

LAYER 1 · COMMODITY

Physical hardware

The heater, the install labor. Near-zero margin at scale — the least attractive part of the business. It exists to create the other three layers.

LAYER 2 · HIGHEST ROE

Asset origination

The spread between deploying a node and the discounted value of its contracted compute stream — Carvana's gain-on-sale analog, recognized conservatively (see pre-mortem).

LAYER 3 · CONVERSION

Structuring & distribution

Bundle nodes into rated tranches; sell ten years of future compute cash for capital today. Fees accrue to whoever structures — a bank partner first, in-house later.

LAYER 4 · THE MOAT

Servicing & orchestration

Sticky, recurring, never sold. Investors can own the cash flows, but **only Superheat can operate the fleet** — routing workloads, guaranteeing uptime, clipping 0.5–2%/yr of node value, forever.

WHERE WE STAND

Proof, and an Honest Baseline.

1,000+

Units deployed

Real homes & commercial installs across
North America

\$550K+

Passive income generated

Validated, real-world fleet revenue to date

~1.0

Effective PUE

Cooling cost: zero. Heat is the product, not
the waste.

100M

Devices by 2030

Manhattan alone $\approx$ 120–150 large data
centers of standing heat demand

Read the second stat honestly: $\approx$ \$300–600 per unit-year realized — largely bitcoin-era units on residential hot-water duty cycles. That matches the residential-DHW row of the model, not the v3.5 headline of \$34K. The fleet that gets financed must be built on metered commercial AI workloads — and proving that is exactly what Phase 1 is for.

What Compute Actually Pays.

GPU	VRAM	MEDIAN \$/HR	RANGE	SUPPLY
B200	192 GB	\$4.06	3.44 - 7.45	High
H200	141 GB	\$3.55	1.97 - 7.89	High
H100 SXM	80 GB	\$2.00	1.47 - 3.93	Med
RTX 5090	32 GB	\$0.53	0.21 - 53.33	High
RTX 4090	24 GB	\$0.40	0.13 - 12.00	High
RTX 3090	24 GB	\$0.16	0.08 - 1.33	High

Interruptible tier -50%+ · reserved 1/3/6-month terms up to -50% · the platform keeps 25-35% of host earnings. The v3.5 deck assumed \$0.49/hr flat for ten years. The market says **\$0.40 — and falling.**

THE UNDERWRITING INPUT THAT MATTERS

Prices Fall. Underwrite the Curve.

–78%

RTX 4090 rentals since mid-2024

\$1.84 → \$0.40/hr on the marketplace floor;
–30% within 4 months of the 5090 launch

–64%

H100 from peak

\$8 → ~\$3/hr. Not monotonic: 1-yr contract rates
bounced +40% Oct '25 → Mar '26 on renewed
demand

–20%/yr

Our sizing assumption

Base case (–30%/yr stress), 5–6-year revenue life
per GPU generation

A flat price for ten years is not financeable. A declining curve with fast amortization is. Every number after this slide bakes it in.

RECALCULATED • FULL UNIT COST

The Whole Box, Costed.

COMPONENT	8 × RTX 4090 BUILD	6 × RTX 5090 BUILD
GPUs (2026 street: 4090 ≈ \$1.8K · 5090 ≈ \$2.4K)	\$14,400	\$14,400
Thermal BOM — tank, heat exchanger, immersion loop, power electronics, networking, enclosure	\$2,500	\$2,500
Install — plumber + electrician	\$1,100	\$1,100
Installed CAPEX	\$18,000	\$18,000
Gross @ 100% util, median rate	\$28.0K / yr	\$27.9K / yr

Both builds = 3.3 kW thermal, identical to H1 spec. The GPU price crash cut installed cost ~43% vs. the v3.5 deck’s \$3,500-per-card era while cutting revenue only ~18% — falling silicon is a **deployment tailwind**. The 5090 build wins going forward: newer silicon decays slower, and there are two fewer cards to service.

RECALCULATED • PER-UNIT REVENUE

Honest Numbers.

SCENARIO	ASSUMPTIONS	NET / UNIT-YR	VS V3.5
Deck v3.5	\$0.49 · 100% util · no fees · no electricity	\$34.3K	—
Spot ceiling	\$0.40 · 100% util · no fees	\$28.0K	−18%
Commercial base ★	60% util · 25% fee · 70% heat-overlap	\$11.7K	−66%
Commercial high	80% util, same fees	\$15.6K	−54%
Residential + space heat	12,000 kWh/yr thermal load	\$8.5K	−75%
Residential DHW-only	4,500 kWh/yr hot water	\$2.3K	−93%
Debt-sizing stress	50% util · price −30%	\$6.8K	−80%

★ = the case every financing number runs on. The fleet's own \$550K proof point sits on the residential-DHW row — which is exactly why the securitized pools get built from **commercial** units.

THE PHYSICS OF THE MARGIN

Free Electricity Has Hours.

Electricity is only free while the host actually wants heat — it's an embedded heating bill, not a compute cost. A family home's hot water absorbs ~16% of the unit's 28,900 kWh/yr thermal output. A hotel absorbs nearly all of it.

16%

Home, hot water only

Consumer product. Financed at point of sale — not a yield asset.

~45%

Cold-climate home + space heat

Strong consumer economics; the payment-offset story.

85%+

Hotels · apartments · campuses

Near-continuous draw. This is the securitizable asset.

Off-heat hours still run compute at retail power — ~\$0.07/GPU-hr cost against a ~\$0.30 net rate. Thinner margin, never negative when rented. The tank itself is a thermal battery: scheduling shifts heating into rented hours.

Smaller Than v3.5. Strong Enough to Lever.

18_{mo}

Payback, commercial base

Was 9.8 mo in v3.5; traditional cloud still takes ~1.5–2× longer

45%

Unlevered IRR

\$44.3K six-year cash on \$18K in — price decline included

+\$14.5K

NPV per unit @ 12%

Year 5–6 GPU module swap restarts the curve at then-current card prices

\$1.47M

Net/yr per 1,000 GPUs

125 units, \$2.25M fully installed — cheaper than v3.5's GPU-only \$3.5M

Per-unit net cash, commercial base case, 20%/yr price decline. The curve is the honest shape of the asset — and the reason the debt amortizes in 5–6 years, not 25.

THE PITCH TO CAPITAL MARKETS

Better Collateral Than Solar or Auto Paper.

Demand is **non-discretionary**

People heat water whether or not AI is in fashion. Margins survive a compute-price downturn that would wipe out a pure data-center borrower.

Structurally **lower opex**

Near-1.0 PUE — no cooling bill in the pool's underlying assets. Lower opex → fatter excess spread → safer senior tranches.

Naturally **diversified**

Thousands of nodes across thousands of buildings and grids. The opposite of a \$2B single-campus data-center loan.

Dual **collateral**

If compute economics soften, the unit is still a working water heater with standalone value. The downside asset is real, not stranded silicon.

Hardware-light **scaling**

Nodes deploy room by room, continuously — feeding continuous issuance instead of lumpy multi-year build cycles.

It **pays the borrower**

Solar loans only cost the homeowner. The H1's income offsets the payment — a credit story no other home-improvement asset has.

FINANCING ARCHITECTURE

Two Assets. Two Machines.

PRODUCT A

Residential → Loan Machine

Customer owns the unit. \$6–9K installed, financed $\sim 12.5\%$ APR $\times$ 10 yr $\approx$ \$88–132/mo. The compute share offsets the payment — up to fully. Superheat keeps hardware margin + origination + servicing; the loan lives on someone else's balance sheet.

Template: GoodLeap home-improvement ABS. Water heaters are already an eligible asset class.

PRODUCT B

Commercial → Yield Machine

Superheat owns the unit (third-party ownership). Host signs a 10-yr heat-services agreement: discounted heat, minimum draw, space + meter. Units sit in a bankruptcy-remote SPV; compute revenue + heat fees fund asset-backed notes.

Template: Sunrun lease structure $\times$ CoreWeave GPU collateral package.

One orchestration & servicing layer underneath both. It is never sold.

CAPITAL PLAN

The Ladder, Sequenced.

RUNG	INSTRUMENT	SIZE	COST	WHEN
0	Equity pilot fleet — build the metered tape	\$2-5M	equity	now
1	Venture debt / equipment lines	\$5-15M	10-14%	6-12 mo
2	Warehouse SPV — revolving, asset-backed	\$15-50M	SOFR+250-450	12-24 mo
3	Forward flow — residential loans sold at par	run-rate	fees retained	18-30 mo
4	Term ABS — 144A takeout	\$150-400M	~S+220 (solar comp)	24-36 mo
5	Programmatic + IG path	\$0.5-1B/yr	A3 is proven (CoreWeave)	36 mo+

Warehouse = a revolving loan to a bankruptcy-remote SPV that holds assets until a term takeout — keep the upside, bear performance risk. **Forward flow** = a committed sale at par as originated — the buyer’s balance sheet funds growth, Superheat keeps origination + servicing fees. Run both: flow for residential volume, warehouse → ABS for the commercial fleet.

PRODUCT A • RESIDENTIAL

Loans That Pay Themselves.

\$110~~0~~/mo

Payment on \$7.5K, 10 yr

Customer's compute share runs \$96–350/mo — offset to fully covered. Cold-climate hydronic homes: the heater pays its own mortgage.

\$2.8–5.3K

Superheat economics / placement

Hardware margin \$2–4K + origination fee 2–5% + dealer spread + servicing strip NPV — mostly cash up front

757

FICO in the template pool

GoodLeap 2026-1: 37,987 loans · \$11,960 avg · 12.56% WAC · \$408.9M raised, 21.9% Class-A enhancement

1 • Partner-originate (GoodLeap seat)

2 • Captive origination

3 • Forward flow at par

4 • Own shelf past \$200M/yr

An H1 loan is the same paper as GoodLeap's — home-improvement loan, prime homeowner, UCC-1 on the fixture — **plus an income-producing asset behind it**. Strictly better credit than a window or HVAC loan, because the collateral generates the cash that supports the payment.

The Securitizable Core.

Host signs 10-yr HSA →

AssetCo SPV owns units →

Compute + heat fees + VPP →

Waterfall →

Noteholders →

Residual to Superheat

75%

Advance rate target

\$13.5K of debt per \$18K unit. Sunrun prints 79.3% on a 20-yr asset; we size conservatively on a 6-yr one

3.5x / 2.0x

DSCR base / stressed

5-yr amortizing at ~9% = \$3.47K/yr debt service.
At 50% utilization and -30% price, still covered twice over

A3

The collateral precedent

CoreWeave's \$8.5B GPU-backed DDTL: investment grade, SOFR+225 — GPUs in an SPV clear credit committees

SPV pledges: equipment (UCC-1), HSA contracts, compute receivables, platform accounts, SPV equity. Two cash legs per unit — variable compute revenue plus fixed contracted heat fees (\$40–80/mo) and VPP income. **The fixed leg anchors the rating; the compute leg is the excess spread.**

PRODUCT C • OPTIONAL ACCELERANT

Finance the Hosts. A Third Asset Feed.

Vast.ai already runs **“Vast Finance”** — matching GPU hosts with equipment-collateral leases, revenue-based loans, and sale-leasebacks, underwritten on verified platform earnings. Lenders already finance hosts on these rails.

Who **borrows**

Franchised installers and building owners who want to own units themselves — the commercial channel that doesn't fit TPO.

What **secures it**

The unit plus assigned compute earnings — the same verified-earnings underwriting Vast Finance proved.

What it **creates**

Yet another securitizable receivable, originated off Superheat's balance sheet. Same machine, third asset feed.

Also in the lease toolbox: Dell Financial Services / HPE Financial Services run as-a-service GPU programs — leasing the compute modules shifts CAPEX off the SPV and simplifies the year-5 refresh covenant.

Compute & Thermal Trust 2027-1.

CLASS	SIZE	TARGET RATING	ENHANCEMENT	COUPON (IND.)	WHO BUYS
A — senior	\$105M	A / A-	~30%	S + 200-250	Insurers, pensions
B — mezz	\$30M	BBB-	~12%	S + 350-450	Asset managers, structured credit
C — junior	\$15M	BB	~4%	S + 600-700	Hedge funds, specialty credit
Residual	retained	—	—	excess spread	Superheat — forever

Pool: 10,000 seasoned commercial units (≥12-mo metered history) · \$180M cost basis · ~\$120M yr-1 collections. ~20% OC (Sunrun comp: 19.5%) · 6-mo liquidity reserve · funded GPU-refresh reserve — our analog of solar’s inverter-replacement reserve · 5–6-yr amortization matched to GPU life, not solar’s 25 · DSCR <1.5× → turbo amortization · platform >60% → cash trap · minimum metered-uptime SLA · named backup servicer. **Rating calibration:** A/A- is the comp-set print, not conservatism — GoodLeap 2026-1 (A-/BBB/BB-), Sunrun 2026 (A-), Vantage (A-), CoreWeave (A3). AA/AAA exists only for seasoned paper (Mosaic, on upgrade) — that’s deals 3–5, not deal one.

MARKET READINESS

The Rulebook Now Exists.

\$57B

US data-center securitization since '21

~\$26B in 2025 alone; sell-side projects \$30–40B/yr through '27

4/4

Agencies with criteria

KBRA Jan '26 · Moody's Feb '25 · S&P '24/'25 ·
Fitch drafts '25 — none of this existed two years ago

10,000

Sites in one pool

Every other deal is single-campus risk. A distributed pool is a portfolio-construction gift to a starved buyer base

Engage KBRA + one of Moody's/S&P at warehouse stage, metered tape in hand — KBRA already rates the GoodLeap shelf, our residential analog. Target: **rated deal within 12 months of warehouse close.**

Manufacture Contracted Dollars.

Solar's most profitable layer was never the electricity — it was monetizing incentives and contracts. Every contracted GPU-hour and hedged dollar moves the rating up and the coupon down.

Demand response / VPP

\$20–100 per unit-year of utility-grade income. EnergyHub already aggregates water heaters for 30+ utilities — the integration is pre-built for our device class. DOE prices VPP capacity at ~half a gas peaker. At 100K units: \$2–10M/yr contracted.

Reserved compute

1/3/6-month committed terms convert spot exposure into contract. SF Compute's forward market can sell 12–24-month strips on a fleet slice. Covenant: $\geq 30\%$ of fleet GPU-hours contracted by deal close.

Heat-services agreements

Minimum-draw clauses are contracted commodity sales — heat-as-a-service, the direct analog of a solar PPA, on every commercial unit.

Incentives at origination

Efficiency rebates, electrification programs, accelerated depreciation packaged into tax-equity partnerships, Luxor hashprice forwards on legacy ASIC units — monetized up front, GoodLeap-style, to compress the CAPEX basis.

THE LENDER CLUB ALREADY EXISTS

\$20B of GPU Debt Has Already Priced This.

\$8.5B

CoreWeave DDTL, rated A3

\$2.3B ('23) → \$7.5B ('24, Blackstone/Magnetar)
→ investment grade ('26), against clusters +
\$19.2B backlog

\$500M

Macquarie → Lambda

Pure GPU-collateral facility from an equipment-
finance house — our strongest warehouse
alternative

60–70%

Used-H100 residual value, 2025

The collateral-recovery anchor; we underwrite
consumer cards at a conservative 30–40%

The NVIDIA track, in three asks: Inception membership now → NVentures
strategic equity at Phase 2 → a **capacity backstop on fleet GPU-hours** — the
CoreWeave precedent (\$6.3B through 2032) and the single most rating-positive
contract Superheat could sign.

The CoreWeave syndicate — Coatue, Carlyle, CDPQ, DigitalBridge, BlackRock funds, Eldridge —
is the full distribution list for Superheat's eventual rated paper. Superheat's pool is stronger on
diversification (thousands of obligors vs. one hyperscaler), weaker on contract tenor — which is
exactly what the HSA fixed leg compensates for.

Name the Failure Modes First.

RISK	REALITY	STRUCTURAL ANSWER
Price decline	4090 -78% in two years; H100 -64% from peak	-20/-30%/yr in sizing · 5-6-yr amortization · turbo triggers · funded refresh reserve
Utilization shortfall	Fleet history ≈ \$550/unit-yr, far below model	Only seasoned, metered commercial units enter pools · reserved-instance floor
Thermal-demand shortfall	Free power exists only when heat is needed	HSA minimum-draw covenants · commercial-first · tank-as-battery scheduling
Platform dependence	One marketplace’s rules hit the whole pool	Multi-platform covenant · 60% concentration cash trap · direct enterprise contracts
Issuance freeze	The 2008 / Carvana failure mode	Growth gated by committed facilities ≥12 months of origination — never assumed take-out
Gain-on-sale optics	Carvana’s credibility trap	Conservative recognition · quarterly static-pool curves · retained residual (skin in the game)
Servicer concentration	“Only Superheat can run it”	Backup-servicer agreement + escrowed orchestration runbooks & code
Refresh execution	The year-5 GPU swap must actually happen	Reserve funded inside the trust · modular hardware design requirement

Why the Dead Died.

Why We Won't.

FAILURE	WHO IT KILLED	OUR COUNTER
Monoline ABS dependence — one revenue leg, assumed take-out	Mosaic (Ch.11 '25) · Sunlight (Ch.11 '23) · Sunnova (Ch.11 '25)	Hardware margin + servicing + compute are independent legs; growth gated by committed capital
Hidden dealer fees — AG suits, tainted shelves	MN AG vs GoodLeap/Sunlight/Mosaic/Dividend — \$35M of hidden fees	Published, transparent dealer fee; income-producing collateral removes the need to stuff fees
Duration mismatch — 25-yr paper funded short into a rate spike	Mosaic's failed refinancing	5–6-yr amortizing structures matched to GPU life
Collateral that only costs the borrower	Every solar-loan book	The H1 pays the borrower — payment offset is the feature no solar lender ever had

These aren't partners; they're structure lessons. The pattern is always the same: equity-funded growth leaning on an ABS market that one day says no.

EXECUTION

Four Phases to a Self-Funding Machine.

PHASE 1 · NOW → 12 MO

Build the **tape**

1–2K commercial units (\$18–36M, equity + venture debt). Meter everything: GPU-hours, realized \$/hr, utilization, uptime, thermal draw. Residential launches through a partner originator at zero balance-sheet cost. **Exit: 12 months of clean tape on ≥1,000 units, ≥30% contracted revenue.**

PHASE 2 · 12–24 MO

Warehouse + **forward flow**

\$25–50M revolving facility against the seasoned fleet (~70–75% advance); residential forward-flow commitments signed; KBRA/Moody's pre-engaged; fleet-wide VPP enrollment. **Exit: warehouse ≥70% utilized, DSCR ≥2.5× trailing six months.**

PHASE 3 · 24–36 MO

Inaugural **ABS**

\$150M Trust 2027-1 as specified. Proceeds recycle into the next 8–10K units. Servicing strip and residual stay home. **Exit: priced inside S+300 blended, advance ≥75%.**

PHASE 4 · 36 MO+

Programmatic

2–4 deals/yr, residential and commercial shelves separate, IG senior classes on the CoreWeave precedent. At 100K units: **~\$1.2B/yr collections supporting ~\$1.4B of standing ABS** — growth compounds on other people's balance sheets.

CAPITAL STRATEGY

This Stage Doesn't Need VCs. It Needs Asset People.

The value is cheap leverage, origination volume, and a retained servicing annuity. Generalist VCs price software growth — they can't provide leverage, and every unit funded with equity instead of debt destroys the ROE story. The monoline solar originators that leaned on equity plus assumed ABS take-out are all in Chapter 11.

POS lenders

Warehouse platforms

Forward-flow buyers

GPU-literate credit

Hybrid + infra equity

Strategics

Six lanes, one cap-table principle: equity only where it buys the tape and the first-loss position; everything that scales is debt.

VALIDATION

They Already Paid for This Thesis.

WHO	WHAT THEY DID	WHAT IT PROVES
Upper90	First institutional capital into Crusoe — the canonical energy-compute crossover	Hybrid funds back energy-compute originators
Generate Capital	Up to \$100M facility to Soluna ('25)	Infra capital lends against compute-energy cash flows
Octopus Energy	£200M into Deep Green ('24); Kraken across millions of homes	Utilities write 9 figures for heat-reuse compute
British Gas / Centrica	Live Heata trial — compute on domestic hot-water cylinders ('25)	Our exact form factor, utility-piloted — at ARM-server scale; H1's GPU economics are an order bigger
Macquarie	\$500M GPU-collateral loan to Lambda	GPUs clear credit committees
Castlelake	\$9B+ of forward flows — Upstart x3 renewals, Pagaya, Alma	Flow buyers renew when the tape performs
NVIDIA	Backstops \$6.3B of CoreWeave capacity through '32; ~\$1B/yr via NVentures	The vendor will anchor demand
A2A / Qarnot	Digital-boiler heat feeding Milan district heating; ADEME-funded €35M	EU district-heating + public-capital templates exist

COUNTERPARTY MAP

Six Lanes, Pre-Scouted.

LANE	LEAD TARGET	BENCH
Residential origination	GoodLeap	GreenSky (Sixth Street) · Service Finance (Truist) · Synchrony · Wisetack/Hearth · Cross River for captive phase
Warehouse	ATLAS SP (Apollo)	Jefferies · Goldman · Citi/CIBC (GoodLeap's bookrunners) · MUFG/SocGen · Victory Park · Ares ABF
Forward flow	Castlelake	Blue Owl/Atalaya · Sixth Street · Fortress · PIMCO · insurance: Athene, Eldridge, MassMutual
GPU-literate debt	Macquarie	Magnetar · Blackstone · the CoreWeave syndicate · Dell/HPE Financial Services
Equity / first-loss	Upper90 + Generate	Spring Lane · HASI · CoVenture · i80 · Architect · Tacora
Strategic / demand	NVIDIA · Octopus	Centrica · Rheem/Navien · KEPCO/Tokyo Gas · EnergyHub · Renew Home · SF Compute · Luxor

These lanes are open now: ATLAS SP printed first-time-originator warehouses this quarter (Wayflyer \$250M, Feb '26); Castlelake renewed Upstart three times; Octopus wrote £200M for a weaker version of this thesis.

ACTION

The First Ten Calls.

01 Upper90

Lead \$10–20M hybrid equity + first-loss. They did Crusoe — thirty-second pitch.

02 Generate Capital

Programmatic project capital for commercial TPO units. They just did Soluna.

03 GoodLeap

H1 as an approved financed product. 500-loan pilot through their contractor app.

04 ATLAS SP

\$25–50M warehouse term sheet on the seasoned commercial fleet.

05 Castlelake

Forward-flow LOI, contingent on the 12-month tape.

06 NVIDIA

Inception now; backstop conversation past 10K GPUs.

07 Octopus Energy

UK/EU strategic round + Kraken-channel pilot.

08 Spring Lane

\$20–30M project equity for the missing middle.

09 EnergyHub

Fleet-wide VPP enrollment — the Rheem integration as template.

10 Macquarie

GPU-collateral warehouse alternative. Keeps ATLAS honest.

At live prices a unit nets ~\$12K/yr — a third of the v3.5 headline, and finally **underwritable**: 18-month payback, 45% IRR, 2× coverage under full stress.

> ORIGINATE. PACKAGE. SELL. REPEAT_

The heater is the commodity.
The manufactured cash flow
is the business.

Full numbers, structures & sources → three companion docs in this folder · Superheat™ · 06.2026
